Barry: your to-go motif accountant

This repository contains a C++ template library that essentially counts sufficient statistics on binary arrays. Its primary goal is to provide a general framework for building discrete exponential-family models. A particular example is Exponential Random Graph Models (ERGMs), but we can use barry to deal with non-square arrays.

Among the key features included in barry, we have:

- Sparse arrays.
- User-defined count statistics.
- User-defined constrain of the support set.
- Powerset generation of binary arrays.
- Discrete Exponential Family Models module (DEFMs).
- Pooled DEFMs.

To use barry, you can either download the entire repository or, since it is header-only, the single header version barry.hpp.

This library was created and maintained by Dr. George G. Vega Yon as part of his doctoral dissertation "Essays on Bioinformatics and Social Network Analysis: Statistical and Computational Methods for Complex Systems."

Examples

Counting statistics in a graph

In the following code we create an array of size 5x5 of class `Network` (available in the namespace `netcounters`), add/remove ties, print the graph, and count common statistics used in ERGMs:

```
#include <iostream>
#include <ostream>
#include "../include/barry.hpp"
typedef std::vector< unsigned int > vuint;
int main() {
  // Creating network of size six with five ties
  netcounters::Network net(
      6, 6,
      {0, 0, 4, 4, 2, 0, 1},
      {1, 2, 0, 2, 4, 0, 1}
  );

  // How does this looks like?
  net.print("Current view");

  // Adding extra ties
  net += {1, 0};
  net(2, 0) = true;

  // And removing a couple
  net(0, 0) = false;
  net -= {1, 1};
  net.print("New view");

  // Initializing the data. The program deals with freing the memory
  net.set_data(new netcounters::NetworkData, true);
  // Creating counter object for the network and adding stats to count
  netcounters::NetStatsCounter counter(&net);
  netcounters::counter_edges(counter.counters);
  netcounters::counter_ttriads(counter.counters);
  netcounters::counter_isolates(counter.counters);
  netcounters::counter_ctriads(counter.counters);
  netcounters::counter_mutual(counter.counters);

  // Counting and printing the results
  std::vector< double > counts = counter.count_all();

  std::cout «
    "Edges             : " « counts[0] « std::endl «
    "Transitive triads : " « counts[1] « std::endl «
    "Isolates          : " « counts[2] « std::endl «
    "C triads          : " « counts[3] « std::endl «
    "Mutuals           : " « counts[4] « std::endl;

  return 0;
}
```

Compiling this program using g++

```
g++ -std=c++11 -Wall -pedantic 08-counts.cpp -o counts && ./counts
```

Yields the following output:

```
Current view
[  0,]  1  1  1  .  .  .
[  1,]  .  1  .  .  .  .
[  2,]  .  .  .  .  1  .
[  3,]  .  .  .  .  .  .
[  4,]  1  .  1  .  .  .
[  5,]  .  .  .  .  .  .
New view
[  0,]  .  1  1  .  .  .
[  1,]  1  .  .  .  .  .
[  2,]  1  .  .  .  1  .
[  3,]  .  .  .  .  .  .
[  4,]  1  .  1  .  .  .
[  5,]  .  .  .  .  .  .
Edges             : 7
Transitive triads : 3
Isolates          : 2
C triads          : 1
Mutuals           : 3
```

Features

Efficient memory usage

One of the key features of barry is that it will handle memory efficiently. In the case of pooled-data models, the module for statistical models avoids double-counting support when possible by keeping track of what datasets (networks, for instance) share the same.

More information can be found in the Doxygen website here and in the PDF version of the documentation here.

Chapter 6

Module Documentation

6.1 Counting

Classes

- class NetworkData

  Data class for Networks.
- class NodeData

  Data definition for the `PhyloArray` *class.*
- class Counter< Array_Type, Data_Type >

  A counter function based on change statistics.

6.1.1 Detailed Description

`barry` includes a flexible way to generate counters based on change statistics. Since most of the time we are counting many motifs in a graph, change statistics make a reasonable (and efficient) way to make such counts.

In particular, let the motif be defined as $s(y)$, with y as the binary array. The change statistic when adding cell y_{ij}, i.e. when the cell moves from being emty to have a one, is defined as

$$\delta(y_{ij}) = s^{+}_{ij}(y) - s^{-}_{ij}(y),$$

where $s^{+}_{ij}(y)$ and $s^{-}_{ij}(y)$ represent the motif statistic with and without the ij-cell. For example, in the case of networks, the change statistic for the number of edges is always 1.

To count statistics in an array, the [Counter] class will empty the array, initialize the counters, and then start counting while adding at each step a single cell, until matching the original array.

6.5.1 Detailed Description

Counters for phylogenetic modeling.

Parameters

counters	A pointer to a `PhyloCounters` object (`Counters<PhyloArray, PhyloCounterData>`).

6.5.2 Function Documentation

6.5.2.1 counter_co_opt()

```
void counter_co_opt (
            PhyloCounters * counters,
            uint nfunA,
            uint nfunB,
            unsigned int duplication = DEFAULT_DUPLICATION )  [inline]
```

Function co-opting.

Function co-opting of functions A and B happens when, for example, function B is gained as a new featured leveraging what function A already does; without losing function A. The sufficient statistic is defined as follows:

$$x_{pa}(1-x_{pb})\sum_{i<j}\left[x^p_{ia}(1-x^p_{ib})x^p_{ja}x^p_{jb}+x^p_{ja}(1-x^p_{jb})x^p_{ia}x^p_{ib}\right]$$

8.1.1 Detailed Description

template<typename Cell_Type = bool, typename Data_Type = bool>
class BArray< Cell_Type, Data_Type >

Baseline class for binary arrays.

`BArray` class objects are arbitrary arrays in which non-empty cells hold data of type `Cell_Type`. The non-empty cells are stored by row and indexed using `unordered_map`s, i.e. `std::vector< std::unordered_map<unsigned int,Cell_Type> >`.

Template Parameters

Cell_Type	Type of cell (any type).
Data_Type	Data type of the array (bool default).

8.1.5 Member Data Documentation

8.1.5.1 visited

```
template<typename Cell_Type = bool, typename Data_Type = bool>
bool BArray< Cell_Type, Data_Type >::visited = false
```

This is as a reference, if we need to iterate through the cells and we need to keep track which were visited, we use this as a reference. So that if cell.visited = true and visited = true, it means that we haven't been here yet. Ideally, any routine using this->visited should switch it at the beginning of the routine.

8.4.1 Detailed Description

template<typename Cell_Type = bool, typename Data_Type = bool>
class BArrayDense< Cell_Type, Data_Type >

Baseline class for binary arrays.

`BArrayDense` class objects are arbitrary dense-arrays. The data is stored internally in the `el` member, which can be accessed using the member function `get_data()`, by column.

Template Parameters

Cell_Type	Type of cell (any type).
Data_Type	Data type of the array (bool default).

8.4.5 Member Data Documentation

8.4.5.1 visited

```
template<typename Cell_Type = bool, typename Data_Type = bool>
bool BArrayDense< Cell_Type, Data_Type >::visited = false
```

This is as a reference, if we need to iterate through the cells and we need to keep track which were visited, we use this as a reference. So that if cell.visited = true and visited = true, it means that we haven't been here yet. Ideally, any routine using this->visited should switch it at the beginning of the routine.

8.27.1 Detailed Description

template<typename T = double>
class FreqTable< T >

Frequency table of vectors.

This is mostly used in `Support`. The main data is contained in the `data` double vector. The matrix is stored in a row-wise fashion, where the first element is the frequency with which the vector is observed.

For example, in a model with `k` terms the first k + 1 elements of `data` would be:

- weights
- term 1
- term 2
- ...
- term k

The model includes a total of $N + 1$ nodes, the $+ 1$ beign the root node.

Parameters

annotations	*A vector of vectors with annotations. It should be of length k (number of functions). Each vector should be of length N (equal to the number of nodes, including interior). Possible values are 0, 1, and 9.*
geneid	*Id of the gene. It should be of length N.*
parent	*Id of the parent gene. Also of length N*
duplication	*Logical scalar indicating the type of event (true: duplication, false: speciation.)*

The ordering of the entries does not matter. Passing the nodes in post order or not makes no difference to the constructor.

Geese prediction

Calculate the conditional probability

Parameters

par	*Vector of parameters (terms + root).*
res_prob	*Vector indicating each nodes' state probability.*
leave_one_out	*When `true`, it will compute the predictions using leave-one-out, thus the prediction will be repeated nleaf times.*
only_annotated	*When `true`, it will make the predictions only on the induced sub-tree with annotated leafs.*
use_reduced_sequence	*Passed to the `likelihood` method.*
preorder	*For the tree traversal.*

When `res_prob` is specified, the function will attach the member vector `probabilities` from the `Node`s objects. This contains the probability that the ith node has either of the possible states.

Returns

std::vector< double > Returns the posterior probability

- std::vector< std::vector< double > > predict (const std::vector< double > &par, std::vector< std::vector< double > > *res_prob=nullptr, bool leave_one_out=false, bool only_annotated=false, bool use_reduced↩_sequence=true)

Likelihood functions.

Calculation of likelihood functions is done reusing normalizing constants. Before recalculating the normalizing constant, the function checks whether `params` *matches the last set vector of parameters used to compute it.*

Parameters

params	*Vector of parameters*
as_log	*When `true`, the function returns the log-likelihood.*

- double likelihood (const std::vector< double > &params, const uint &i, bool as_log=false)
- double likelihood (const std::vector< double > &params, const Array_Type &Array_, int i=-1, bool as_log=false)
- double likelihood (const std::vector< double > &params, const std::vector< double > &target_, const uint &i, bool as_log=false)
- double likelihood (const std::vector< double > &params, const double *target_, const uint &i, bool as_log=false)
- double likelihood_total (const std::vector< double > &params, bool as_log=false)

Extract elements by index

Parameters

i	*Index relative to the array in the model.*
params	*A new vector of model parameters to compute the normalizing constant.*
as_log	*When `true` returns the logged version of the normalizing constant.*

- double get_norm_const (const std::vector< double > &params, const uint &i, bool as_log=false)
- const std::vector< Array_Type > * get_pset (const uint &i)
- const std::vector< double > * get_pset_stats (const uint &i)

Size of the model

Number of different supports included in the model

This will return the size of `stats_target`.

Returns

`size()` returns the number of arrays in the model.
`size_unique()` returns the number of unique arrays (according to the hasher) in the model.
`nterms()` returns the number of terms in the model.

- bool delete_rules_dyn = false
- std::function< std::vector< double >double *, unsigned int k)> transform_model_fun = nullptr

  Transformation of the model.
- std::vector< std::string > transform_model_term_names

Random number generation

Random number generation

- std::mt19937 * rengine = nullptr
- bool delete_rengine = false

Information about the arrays used in the model

`stats_target` *holds the observed sufficient statistics for each array in the dataset.* `array_frequency` *contains the frequency with which each of the target stats_target (arrays) shows in the support.* `array2support` *maps array indices (0, 1, ...) to the corresponding support.*

Each vector of `stats_support` *has the data stored in a row-wise order, with each row starting with the weights, e.g., in a model with* `k` *terms the first k + 1 elements of* `stats_support` *would be:*

- *weights*
- *term 1*
- *term 2*
- *...*
- *term k*

- std::vector< std::vector< double > > stats_support

  Sufficient statistics of the model (support)
- std::vector< uint > stats_support_n_arrays

  Number of arrays included per support.
- std::vector< std::vector< double > > stats_target

  Target statistics of the model.
- std::vector< uint > arrays2support

Container space for the powerset (and its sufficient stats_target)

This is useful in the case of using simulations or evaluating functions that need to account for the full set of states.

- bool with_pset = false
- std::vector< std::vector< Array_Type > > pset_arrays
  Arrays of the support(s)
- std::vector< std::vector< double > > pset_stats
  Statistics of the support(s)
- std::vector< std::vector< double > > pset_probs
  Probabilities of the support(s)

- Rules< Array_Type, Data_Rule_Dyn_Type > * rules_dyn
- Support< Array_Type, Data_Counter_Type, Data_Rule_Type, Data_Rule_Dyn_Type > support_fun
- StatsCounter< Array_Type, Data_Counter_Type > counter_fun

8.29.1 Detailed Description

template<typename Array_Type = BArray<>, typename Data_Counter_Type = bool, typename Data_Rule_Type = bool, typename Data_Rule_Dyn_Type = bool>
class Model< Array_Type, Data_Counter_Type, Data_Rule_Type, Data_Rule_Dyn_Type >

General framework for discrete exponential models. This class allows generating discrete exponential models in the form of a linear exponential model:

$$\frac{\exp\left(\theta^{\mathsf{t}} c(A)\right)}{\sum_{A' \in \mathcal{A}} \exp\left(\theta^{\mathsf{t}} c(A')\right)}$$

This implementation aims to reduce the number of times that the support needs to be computed. Models included here use more than a single array, and thus allow the function to recycle support sets as needed. For example, if we are looking at directed graphs all of the same size and without vertex level features, i.e. a model that only counts edges, triangles, etc. then the support needs to be fully computed only once.

Template Parameters

Array_Type	Class of `BArray` object.
Data_Counter_Type	Any type.
Data_Rule_Type	Any type.

8.29.3.1 add_array()

```
template<typename Array_Type = BArray<>, typename Data_Counter_Type = bool, typename Data_↩
Rule_Type = bool, typename Data_Rule_Dyn_Type = bool>
uint Model< Array_Type, Data_Counter_Type, Data_Rule_Type, Data_Rule_Dyn_Type >::add_array (
            const Array_Type & Array_,
            bool force_new = false )
```

Adds an array to the support of not already included.

Parameters

*Array_*	array to be added
force_new	If `false`, it will use `keygen` to obtain a double vector and create a hash of it. If the hash has been computed earlier, the support is recycled.

Returns

The number of the array.

Raw pointers to the support and target statistics.

The support of the model is stored as a vector of vector<double>. Each element of it contains the support for an specific type of array included. It represents an array of size `(k + 1) x n unique elements`, with the data stored by-row. The last element of each entry corresponds to the weights, i.e., the frequency with which such sufficient statistics are observed in the support.

- `data` Pointer to the first element of the set of sufficient statistics
- `k` unsigned int indicating the number of sufficient statistics

Returns

Nothing, but it will modify the model data.

8.41.1 Detailed Description

template<typename Array_Type = BArray<bool, bool>, typename Data_Counter_Type = bool, typename Data_Rule_Type = bool, typename Data_Rule_Dyn_Type = bool>
class Support< Array_Type, Data_Counter_Type, Data_Rule_Type, Data_Rule_Dyn_Type >

Compute the support of sufficient statistics.

Given an array and a set of counters, this object iterates throughout the support set of the Array while at the same time computing the support of the sufficient statitics.

The members `rule` and `rule_dyn` allow constraining the support. The first will establish which cells of the array will be used to iterate, for example, in the case of social networks, self-loops are not allowed, so the entire diagonal would be fixed to zero, reducing the size of the support.

In the case of `rule_dyn`, the function will stablish dynamically whether the current state will be included in the counts or not. For example, this set of rules can be used to constrain the support to networks that have a prescribed degree sequence.

Configuration MACROS

These are mostly related to performance. The definitions follow:

- `BARRY_USE_UNORDERED_MAP` If specified, then barry is compiled using `std::unordered_map`. Otherwise it will use `std::map` for the arrays.
- `BARRY_USE_SAFE_EXP` When specified, it will multiply all likelihoods in `Model` by (1/-100)/(1/-100) so that numerical overflows are avoided.
- `BARRY_USE_ISFINITE` When specified, it will introduce a macro that checks whether the likelihood is finite or not.
- `printf_barry` If not specified, will be defined as `printf`.
- `BARRY_DEBUG_LEVEL`, when defined, will make things verbose.

- #define BARRY_SAFE_EXP -100.0
- #define BARRY_ISFINITE(a)
- #define BARRY_CHECK_SUPPORT(x, maxs)

Functions

- void defm_motif_parser (std::string formula, std::vector< size_t > &locations, std::vector< bool > &signs, size_t m_order, size_t y_ncol)

  Parses a motif formula.

9.27.1 Function Documentation

9.27.1.1 defm_motif_parser()

```
void defm_motif_parser (
            std::string formula,
            std::vector< size_t > & locations,
            std::vector< bool > & signs,
            size_t m_order,
            size_t y_ncol )  [inline]
```

Parses a motif formula.

This function will take the formula and generate the corresponding input for defm::counter_transition(). Formulas can be specified in the following ways:

- Intercept effect: {...} No transition, only including the current state.
- Transition effect: {...} > {...} Includes current and previous states.

The general notation is `[0]y[column id]_[row id]`. A preceeding zero means that the value of the cell is considered to be zero. The column id goes between 0 and the number of columns in the array - 1 (so it is indexed from 0,) and the row id goes from 0 to m_order.

Intercept effects

Intercept effects only involve a single set of curly brackets. Using the 'greater-than' symbol (i.e., '<') is only for transition effects. When specifying intercept effects, users can skip the `row_id`, e.g., `y0_0` is equivalent to `y0`. If the passed `row id` is different from the Markov order, i.e., `row_id != m_order`, then the function returns with an error.

Examples:

- "`{y0, 0y1}`" is equivalent to set a motif with the first element equal to one and the second to zero.

Transition effects

Transition effects can be specified using two sets of curly brackets and an greater-than symbol, i.e., `{...} > {...}`. The first set of brackets, which we call LHS, can only hold `row id` that are less than `m_order`.

Parameters

locations	
signs	
m_order	
y_ncol

Parameters

Array_Type	a BArray
unit,uint	Focal cell
Data_Type	Data associated with the function, for example, id of the attribute in the Array.

Returns

`Counter_fun_type` a double (the change statistic)

`Rule_fun_type` a bool. True if the cell is blocked.
