Barry: your to-go motif accountant

This repository contains a C++ template library that essentially counts sufficient statistics on binary arrays. The goal of the library is to provide a general framework for building discrete exponential-family models. A particular example is Exponential Random Graph Models (ERGMs), but we can use `barry` to deal with non-square arrays.

Among the key features included in `barry`, we have:

- Sparse arrays.
- User-defined count statistics.
- User-defined constrain of the support set.
- Powerset generation of binary arrays.
- Discrete Exponential Family Models module (DEFMs).
- Pooled DEFMs.

Examples

Counting statistics in a graph

In the following code we create an array of size 5x5 of class `Network` (available in the namespace `netcounters`), add/remove ties, print the graph, and count common statistics used in ERGMs:

```
#include <iostream>
#include <ostream>
#include "../include/barry.hpp"
typedef std::vector< unsigned int > vuint;
int main() {
    // Creating network of size six with five ties
    netcounters::Network net(
        6, 6,
        {0, 0, 4, 4, 2, 0, 1},
        {1, 2, 0, 2, 4, 0, 1}
    );
```

```

// How does this looks like?
net.print("Current view");

// Adding extra ties
net += {1, 0};
net(2, 0) = true;

// And removing a couple
net(0, 0) = false;
net -= {1, 1};
net.print("New view");

// Initializing the data. The program deals with freeing the memory
net.set_data(new netcounters::NetworkData, true);
// Creating counter object for the network and adding stats to count
netcounters::NetStatsCounter counter(&net);
netcounters::counter_edges(counter.counters);
netcounters::counter_ttriads(counter.counters);
netcounters::counter_isolates(counter.counters);
netcounters::counter_ctriads(counter.counters);
netcounters::counter_mutual(counter.counters);

// Counting and printing the results
std::vector< double > counts = counter.count_all();

std::cout <<
    "Edges          : " << counts[0] << std::endl <<
    "Transitive triads : " << counts[1] << std::endl <<
    "Isolates        : " << counts[2] << std::endl <<
    "C triads        : " << counts[3] << std::endl <<
    "Mutuals         : " << counts[4] << std::endl;

return 0;
}

```

Compiling this program using g++

```
g++ -std=c++11 -Wall -pedantic 08-counts.cpp -o counts && ./counts
```

Yields the following output:

```

Current view
[ 0,] 1 1 1 . . .
[ 1,] . 1 . . . .
[ 2,] . . . . 1 .
[ 3,] . . . . .
[ 4,] 1 . 1 . . .
[ 5,] . . . . . .
New view
[ 0,] . 1 1 . . .
[ 1,] 1 . . . . .
[ 2,] 1 . . . 1 .
[ 3,] . . . . .
[ 4,] 1 . 1 . . .
[ 5,] . . . . .
Edges          : 7
Transitive triads : 3
Isolates       : 2
C triads       : 1
Mutuals        : 3

```

Features

Efficient memory usage

One of the key features of `barry` is that it will handle memory efficiently. In the case of pooled-data models, the module for statistical models avoids double-counting support when possible by keeping track of what datasets (networks, for instance) share the same.

5.1 Counting

Classes

- class [NetworkData](#)
Data class for Networks.
- class [NodeData](#)
Data definition for the `PhyloArray` class.
- class [Counter](#)`< Array_Type, Data_Type >`
A counter function based on change statistics.

5.1.1 Detailed Description

`barry` includes a flexible way to generate counters based on change statistics. Since most of the time we are counting many motifs in a graph, change statistics make a reasonable (and efficient) way to make such counts.

In particular, let the motif be defined as $s(y)$, with y as the binary array. The change statistic when adding cell y_{ij} , i.e. when the cell moves from being empty to have a one, is defined as

$$\delta(y_{ij}) = s_{ij}^+(y) - s_{ij}^-(y),$$

where $s_{ij}^+(y)$ and $s_{ij}^-(y)$ represent the motif statistic with and without the ij -cell. For example, in the case of networks, the change statistic for the number of edges is always 1.

To count statistics in an array, the [\[Counter\]](#) class will empty the array, initialize the counters, and then start counting while adding at each step a single cell, until matching the original array.

Function co-opting of functions A and B happens when, for example, function B is gained as a new featured leveraging what function A already does; without losing function A. The sufficient statistic is defined as follows:

$$x_{pa}(1 - x_{pb}) \sum_{i < j} \left[x_{ia}^p (1 - x_{ib}^p) x_{ja}^p x_{jb}^p + x_{ja}^p (1 - x_{jb}^p) x_{ia}^p x_{ib}^p \right]$$

7.1.1 Detailed Description

```
template<typename Cell_Type = bool, typename Data_Type = bool>
class BArray< Cell_Type, Data_Type >
```

Baseline class for binary arrays.

`BArray` class objects are arbitrary arrays in which non-empty cells hold data of type `Cell_Type`. The non-empty cells are stored by row and indexed using `unordered_maps`, i.e. `std::vector< std::unordered_map<unsigned int, Cell_Type> >`.

Template Parameters

<i>Cell_Type</i>	Type of cell (any type).
<i>Data_Type</i>	Data type of the array (bool default).

7.1.5 Member Data Documentation

7.1.5.1 visited

```
template<typename Cell_Type = bool, typename Data_Type = bool>
bool BArray< Cell_Type, Data_Type >::visited = false
```

This is as a reference, if we need to iterate through the cells and we need to keep track which were visited, we use this as a reference. So that if cell.visited = true and visited = true, it means that we haven't been here yet. Ideally, any routine using this->visited should switch it at the beginning of the routine.

7.4.1 Detailed Description

```
template<typename Cell_Type = bool, typename Data_Type = bool>
class BArrayDense< Cell_Type, Data_Type >
```

Baseline class for binary arrays.

`BArrayDense` class objects are arbitrary arrays in which non-empty cells hold data of type `Cell_Type`. The non-empty cells are stored by row and indexed using `unordered_maps`, i.e. `std::vector< std::unordered_map<unsigned int, Cell_Type> >`.

Template Parameters

<i>Cell_Type</i>	Type of cell (any type).
<i>Data_Type</i>	Data type of the array (bool default).

7.4.5 Member Data Documentation

7.4.5.1 visited

```
template<typename Cell_Type = bool, typename Data_Type = bool>
bool BArrayDense< Cell_Type, Data_Type >::visited = false
```

This is as a reference, if we need to iterate through the cells and we need to keep track which were visited, we use this as a reference. So that if cell.visited = true and visited = true, it means that we haven't been here yet. Ideally, any routine using this->visited should switch it at the beginning of the routine.

7.14.1 Detailed Description

```
template<typename Array_Type = BArray<>, typename Data_Type = bool>

Various functions hold more than one counter, so this class is a helper class that allows managing multiple counters efficiently. The main data is a vector to pointers of counters.

Construct a new Geese object

The model includes a total of $N + 1$ nodes, the $+ 1$ beign the root node.

Parameters

annotations	A vector of vectors with annotations. It should be of length k (number of functions). Each vector should be of length N (equal to the number of nodes, including interior). Possible values are 0, 1, and 9.
geneid	Id of the gene. It should be of length N .
parent	Id of the parent gene. Also of length N
duplication	Logical scalar indicating the type of event (true: duplication, false: speciation.)

The ordering of the entries does not matter. Passing the nodes in post order or not makes no difference to the constructor.

- `Geese ()`
- `Geese (std::vector< std::vector< unsigned int > > &annotations, std::vector< unsigned int > &geneid, std::vector< int > &parent, std::vector< bool > &duplication)`

Information about the model

Parameters

verb	When <code>true</code> it will print out information about the encountered polytomies.
------	--

- `unsigned int nfuncs () const noexcept`

- *Number of functions analyzed.*
unsigned int [nnodes](#) () **const noexcept**
- *Number of nodes (interior + leaf)*

Geese prediction

Calculate the conditional probability

Parameters

par	Vector of parameters (terms + root).
res_prob	Vector indicating each nodes' state probability.
leave_one_out	When <i>true</i> , it will compute the predictions using leave-one-out, thus the prediction will be repeated <i>nleafs</i> times.
only_annotated	When <i>true</i> , it will make the predictions only on the induced sub-tree with annotated leaves.
use_reduced_sequence	Passed to the <i>likelihood</i> method.
preorder	For the tree traversal.

When *res_prob* is specified, the function will attach the member vector probabilities from the [Nodes](#) objects. This contains the probability that the *ith* node has either of the possible states.

Returns

std::vector< double > Returns the posterior probability

- *std::vector< std::vector< double > >* [predict](#) (**const** std::vector< double > &par, std::vector< std::vector< double > > *res_prob=nullptr, bool leave_one_out=false, bool only_annotated=false, bool use_reduced_sequence=true)

Non-const pointers to shared objects in `<tt>Geese</tt>`

These functions provide direct access to some member objects that are shared by the nodes within [Geese](#).

Returns

[get_counters](#) () returns the vector of counters used.
[get_model](#) () returns the [Model](#) object used.
[get_support](#) () returns the computed support of the model.

Likelihood functions.

Calculation of likelihood functions is done reusing normalizing constants. Before recalculating the normalizing constant, the function checks whether *params* matches the last set vector of parameters used to compute it.

Parameters

params	Vector of parameters
as_log	When <i>true</i> , the function returns the log-likelihood.

- double `likelihood` (`const` std::vector< double > ¶ms, `const` uint &i, bool as_log=false)
- double `likelihood` (`const` std::vector< double > ¶ms, `const` Array_Type &Array_, int i=-1, bool as_log=false)
- double `likelihood` (`const` std::vector< double > ¶ms, `const` std::vector< double > &target_, `const` uint &i, bool as_log=false)
- double `likelihood_total` (`const` std::vector< double > ¶ms, bool as_log=false)

Extract elements by index

Parameters

i	Index relative to the array in the model.
params	A new vector of model parameters to compute the normalizing constant.
as_log	When <i>true</i> returns the logged version of the normalizing constant.

- double `get_norm_const` (`const` std::vector< double > ¶ms, `const` uint &i, bool as_log=false)
- `const` std::vector< Array_Type > * `get_pset` (`const` uint &i)
- `const` std::vector< std::vector< double > > * `get_pset_stats` (`const` uint &i)

Size of the model

Number of different supports included in the model

This will return the size of *stats*.

Returns

`size()` returns the number of arrays in the model.
`size_unique()` returns the number of unique arrays (according to the hasher) in the model.
`nterms()` returns the number of terms in the model.

- unsigned int `size()` `const` noexcept

- std::vector< std::string > `colnames()` `const`

7.19.1 Detailed Description

```
template<typename Array_Type = BArray<>, typename Data_Counter_Type = bool, typename Data_Rule_Type = bool, typename
Data_Rule_Dyn_Type = bool>
class Model< Array_Type, Data_Counter_Type, Data_Rule_Type, Data_Rule_Dyn_Type >
```

General framework for discrete exponential models. This class allows generating discrete exponential models in the form of a linear exponential model:

$$\frac{\exp(\theta^t c(A))}{\sum_{A' \in \mathcal{A}} \exp(\theta^t c(A'))}$$

This implementation aims to reduce the number of times that the support needs to be computed. Models included here use more than a single array, and thus allow the function to recycle support sets as needed. For example, if we are looking at directed graphs all of the same size and without vertex level features, i.e. a model that only counts edges, triangles, etc. then the support needs to be fully computed only once.

Template Parameters

<i>Array_Type</i>	Class of BArray object.
<i>Data_Counter_Type</i>	Any type.
<i>Data_Rule_Type</i>	Any type.

uint Model< Array_Type, Data_Counter_Type, Data_Rule_Type, Data_Rule_Dyn_Type >::add_array (

Adds an array to the support of not already included.

Parameters

<i>Array_</i>	array to be added
<i>force_new</i>	If false, it will use <code>keygen</code> to obtain a double vector and create a hash of it. If the hash has been computed earlier, the support is recycled.

Returns

7.31.1 Detailed Description

```
template<typename Array_Type = BArray<>, typename Data_Counter_Type = bool, typename Data_Rule_Type = bool, typename
Data_Rule_Dyn_Type = bool>
class Support< Array_Type, Data_Counter_Type, Data_Rule_Type, Data_Rule_Dyn_Type >
```

Compute the support of sufficient statistics.

Given an array and a set of counters, this object iterates throughout the support set of the Array while at the same time computing the support of the sufficient statistics.

The members `rule` and `rule_dyn` allow constraining the support. The first will establish which cells of the array will be used to iterate, for example, in the case of social networks, self-loops are not allowed, so the entire diagonal would be fixed to zero, reducing the size of the support.

In the case of `rule_dyn`, the function will establish dynamically whether the current state will be included in the counts or not. For example, this set of rules can be used to constrain the support to networks that have a prescribed degree sequence.
