## Main Page

### Barry: your to-go motif accountant

This repository contains a C++ template library that essentially counts sufficient statistics on binary arrays. The idea of the library is that this can be used together to build exponential family models as those in Exponential Random Graph Models (ERGMs), but as a generalization that also deals with non square arrays.

### Examples

#### Counting statistics in a graph

In the following code we create an array of size 5x5 of class `Network` (available in the namespace `netcounters`), add/remove ties, print the graph, and count common statistics used in ERGMs:

```
#include <iostream>
#include <ostream>
#include "../include/barry.hpp"
typedef std::vector< unsigned int > vuint;
int main() {
    // Creating network of size six with five ties
    netcounters::Network net(
        6, 6,
        {0, 0, 4, 4, 2, 0, 1},
        {1, 2, 0, 2, 4, 0, 1}
    );

    // How does this looks like?
    std::cout << "Current view" << std::endl;
    net.print();

    // Adding extra ties
    net += {1, 0};
    net(2, 0) = true;

    // And removing a couple
    net(0, 0) = false;
    net -= {1, 1};
    std::cout << "New view" << std::endl;
    net.print();

    // Initializing the data. The program deals with freeing the memory
    net.set_data(new netcounters::NetworkData, true);
    // Creating counter object for the network and adding stats to count
    netcounters::NetStatsCounter counter(&net);
    netcounters::counter_edges(counter.counters);
```

```

netcounters::counter_ttriads(counter.counters);
netcounters::counter_isolates(counter.counters);
netcounters::counter_ctriads(counter.counters);
netcounters::counter_mutual(counter.counters);

// Counting and printing the results
std::vector< double > counts = counter.count_all();

std::cout <<
    "Edges          : " << counts[0] << std::endl <<
    "Transitive triads : " << counts[1] << std::endl <<
    "Isolates        : " << counts[2] << std::endl <<
    "C triads        : " << counts[3] << std::endl <<
    "Mutuals         : " << counts[4] << std::endl;

return 0;
}

```

Compiling this program using g++

```
g++ -std=c++11 -Wall -pedantic 08-counts.cpp -o counts && ./counts
```

Yields the following output:

```

Current view
[ 0,] 1 1 1 . . .
[ 1,] . 1 . . . .
[ 2,] . . . . 1 .
[ 3,] . . . . . .

[ 1,] 1 . . . . .
[ 2,] 1 . . . 1 .
[ 3,] . . . . . .
[ 4,] 1 . 1 . . .
[ 5,] . . . . . .
Edges          : 7
Transitive triads : 3
Isolates       : 2
C triads       : 1

```

### 5.1 Counting

#### Classes

- class [NetworkData](#)  
*Data class for Networks.*
- class [NodeData](#)  
*Data definition for the `PhyloArray` class.*
- class [Counter](#)< [Array\\_Type](#), [Data\\_Type](#) >  
*A counter function based on change statistics.*

#### 5.1.1 Detailed Description

`barry` includes a flexible way to generate counters based on change statistics. Since most of the time we are counting many motifs in a graph, change statistics make a reasonable (and efficient) way to make such counts.

In particular, let the motif be defined as  $s(y)$ , with  $y$  as the binary array. The change statistic when adding cell  $y_{ij}$ , i.e. when the cell moves from being empty to have a one, is defined as

$$\delta(y_{ij}) = s_{ij}^+(y) - s_{ij}^-(y),$$

where  $s_{ij}^+(y)$  and  $s_{ij}^-(y)$  represent the motif statistic with and without the  $ij$ -cell. For example, in the case of networks, the change statistic for the number of edges is always 1.

To count statistics in an array, the [\[Counter\]](#) class will empty the array, initialize the counters, and then start counting while adding at each step a single cell, until matching the original array.

Function co-opting of functions A and B happens when, for example, function B is gained as a new featured leveraging what function A already does; without losing function A. The sufficient statistic is defined as follows:

$$x_{pa}(1 - x_{pb}) \sum_{i < j} \left[ x_{ia}^p (1 - x_{ib}^p) x_{ja}^p x_{jb}^p + x_{ja}^p (1 - x_{jb}^p) x_{ia}^p x_{ib}^p \right]$$

## 7.1.1 Detailed Description

```
template<typename Cell_Type = bool, typename Data_Type = bool>
class BArray< Cell_Type, Data_Type >
```

Baseline class for binary arrays.

`BArray` class objects are arbitrary arrays in which non-empty cells hold data of type `Cell_Type`. The non-empty cells are stored by row and indexed using `unordered_maps`, i.e. `std::vector< std::unordered_map<unsigned int, Cell_Type> >`.

#### Template Parameters

<i>Cell_Type</i>	Type of cell (any type).
<i>Data_Type</i>	Data type of the array (bool default).

## 7.1.5 Member Data Documentation

### 7.1.5.1 visited

```
template<typename Cell_Type = bool, typename Data_Type = bool>
bool BArray< Cell_Type, Data_Type >::visited = false
```

This is as a reference, if we need to iterate through the cells and we need to keep track which were visited, we use this as a reference. So that if cell.visited = true and visited = true, it means that we haven't been here yet. Ideally, any routine using this->visited should switch it at the beginning of the routine.

### 7.10.1 Detailed Description

```
template<typename Array_Type = BArray<>, typename Data_Type = bool>
class Counters< Array_Type, Data_Type >
```

Vector of counters.

Various functions hold more than one counter, so this class is a helper class that allows managing multiple counters efficiently. The main data is a vector to pointers of counters.

### Construct a new Geese object

*The model includes a total of  $N + 1$  nodes, the  $+ 1$  beign the root node.*

**Parameters**

annotations	<i>A vector of vectors with annotations. It should be of length <math>k</math> (number of functions). Each vector should be of length <math>N</math> (equal to the number of nodes, including interior). Possible values are 0, 1, and 9.</i>
geneid	<i>Id of the gene. It should be of length <math>N</math>.</i>
parent	<i>Id of the parent gene. Also of length <math>N</math></i>

- unsigned int [nnodes](#) () const noexcept
- unsigned int [nleafs](#) () const noexcept
- unsigned int [nterms](#) () const
- unsigned int [support\\_size](#) () const noexcept

**Geese prediction**

*Calculate the conditional probability*

**Parameters**

par	<i>Vector of parameters (terms + root).</i>
res_prob	<i>Vector indicating each nodes' state probability.</i>
leave_one_out	<i>When <code>true</code>, it will compute the predictions using leave-one-out, thus the prediction will be repeated <code>nleaf</code> times.</i>
only_annotated	<i>When <code>true</code>, it will make the predictions only on the induced sub-tree with annotated leafs.</i>
use_reduced_sequence	<i>Passed to the <code>likelihood</code> method.</i>
preorder	<i>For the tree traversal.</i>

When `res_prob` is specified, the function will attach the member vector probabilities from the [Nodes](#) objects. This contains the probability that the  $i$ th node has either of the possible states.

**Returns**

`std::vector< double >` Returns the posterior probability

#### Likelihood functions.

Calculation of likelihood functions is done reusing normalizing constants. Before recalculating the normalizing constant, the function checks whether `params` matches the last set vector of parameters used to compute it.

##### Parameters

<code>params</code>	Vector of parameters
<code>as_log</code>	When <code>true</code> , the function returns the log-likelihood.

- `double likelihood (const std::vector< double > &params, const uint &i, bool as_log=false)`
- `double likelihood (const std::vector< double > &params, const Array_Type &Array_, int i=-1, bool as_log=false)`
- `double likelihood (const std::vector< double > &params, const std::vector< double > &target_, const uint &i, bool as_log=false)`
- `double likelihood_total (const std::vector< double > &params, bool as_log=false)`

#### Extract elements by index

##### Parameters

<code>i</code>	Index relative to the array in the model.
<code>params</code>	A new vector of model parameters to compute the normalizing constant.
<code>as_log</code>	When <code>true</code> returns the logged version of the normalizing constant.

- double `get_norm_const` (const std::vector< double > &params, const uint &i, bool as\_log=false)
- const std::vector< Array\_Type > \* `get_pset` (const uint &i)
- const std::vector< std::vector< double > > \* `get_stats` (const uint &i)

### Size of the model

*Number of different supports included in the model*

*This will return the size of `stats`.*

#### Returns

`size()` returns the number of arrays in the model.

`size_unique()` returns the number of unique arrays (according to the hasher) in the model.

`nterms()` returns the number of terms in the model.

- unsigned int `size()` const noexcept
- unsigned int `size_unique()` const noexcept
- unsigned int `nterms()` const noexcept
- unsigned int `support_size()` const noexcept

## 7.15.1 Detailed Description

```
template<typename Array_Type = BArray<>, typename Data_Counter_Type = bool, typename Data_Rule_Type = bool, typename
Data_Rule_Dyn_Type = bool>
```

```
class Model< Array_Type, Data_Counter_Type, Data_Rule_Type, Data_Rule_Dyn_Type >
```

General framework for discrete exponential models. This class allows generating discrete exponential models in the form of a linear exponential model:

$$\frac{\exp(\theta^t c(A))}{\sum_{A' \in \mathcal{A}} \exp(\theta^t c(A'))}$$

This implementation aims to reduce the number of times that the support needs to be computed. Models included here use more than a single array, and thus allow the function to recycle support sets as needed. For example, if we are looking at directed graphs all of the same size and without vertex level features, i.e. a model that only counts edges, triangles, etc. then the support needs to be fully computed only once.

#### Template Parameters

<i>Array_Type</i>	Class of <code>BArray</code> object.
<i>Data_Counter_Type</i>	Any type.
<i>Data_Rule_Type</i>	Any type.

### 7.15.3.1 add\_array()

```
template<typename Array_Type , typename Data_Counter_Type , typename Data_Rule_Type , typename Data_Rule_Dyn_Type >
```

```
uint Model< Array_Type, Data_Counter_Type, Data_Rule_Type, Data_Rule_Dyn_Type >::add_array (
    const Array_Type & Array_,
    bool force_new = false ) [inline]
```

Adds an array to the support of not already included.

## Parameters

<i>Array_</i>	array to be added
<i>force_new</i>	If false, it will use <code>keygen</code> to obtain a double vector and create a hash of it. If the hash has been computed earlier, the support is recycled.

## Returns

The number of the array.

When computing with the powerset, we need to grow the corresponding vectors on the fly

### 7.25.1 Detailed Description

```
template<typename Array_Type = BArray<>, typename Data_Counter_Type = bool, typename Data_Rule_Type = bool, typename
Data_Rule_Dyn_Type = bool>
class Support< Array_Type, Data_Counter_Type, Data_Rule_Type, Data_Rule_Dyn_Type >
```

Compute the support of sufficient statistics.

Given an array and a set of counters, this object iterates throughout the support set of the Array while at the same time computing the support of the sufficient statistics.

The members `rule` and `rule_dyn` allow constraining the support. The first will establish which cells of the array will be used to iterate, for example, in the case of social networks, self-loops are not allowed, so the entire diagonal would be fixed to zero, reducing the size of the support.

In the case of `rule_dyn`, the function will establish dynamically whether the current state will be included in the counts or not. For example, this set of rules can be used to constrain the support to networks that have a prescribed degree sequence.

## Configuration MACROS

These are mostly related to performance. The definitions follow:

- `BARRY_USE_UNORDERED_MAP` If specified, then barry is compiled using `std::unordered_map`. Otherwise it will use `std::map` for the arrays.
  - `BARRY_USE_SAFE_EXP` When specified, it will multiply all likelihoods in [Model](#) by  $(1/-100)/(1/-100)$  so that numerical overflows are avoided.
  - `BARRY_USE_ISFINITE` When specified, it will introduce a macro that checks whether the likelihood is finite or not.
  - `printf_barry` If not specified, will be defined as `printf`.
- 
- `#define BARRY_SAFE_EXP -100.0`
  - `#define BARRY_ISFINITE(a)`
  - `#define BARRY_CHECK_SUPPORT(x, maxs)`
  - `#define printf_barry printf`
  - `#define BARRY_MAX_NUM_ELEMENTS static_cast< unsigned int >(UINT_MAX/2u)`
  - `template<typename Ta , typename Tb >`  
`using Map = std::map< Ta, Tb >`

```
#define PHYLO_CHECK_MISSING( )
```

#### Value:

if (data == nullptr) \
throw std::logic_error("The counter/rule data is nullptr.")
```

Definition at line 94 of file phylo.hpp.

```
typedef unsigned int uint
```

Definition at line 10 of file typedefs.hpp.

## 8.41.2 Function Documentation

### 8.41.2.1 vec\_equal()

```
template<typename T >
bool vec_equal (
    const std::vector< T > & a,
    const std::vector< T > & b ) [inline]
```

Compares if -a- and -b- are equal.

#### Parameters

<i>a,b</i>	Two vectors of the same length
------------	--------------------------------

#### Returns

`true` if all elements are equal.

Definition at line 137 of file typedefs.hpp.

### 8.41.2.2 `vec_equal_approx()`

```
template<typename T >
bool vec_equal_approx (
    const std::vector< T > & a,
    const std::vector< T > & b,
    double eps = 1e-10 ) [inline]
```

Definition at line 155 of file typedefs.hpp.

### 8.41.2.3 `vec_inner_prod()`

```
template<typename T >
T vec_inner_prod (
    const std::vector< T > & a,
    const std::vector< T > & b ) [inline]
```
